                                                                                                                                                                                                                                                                                                                                                                                               The present sequence represents a synthetic oligonucleotide HBV43a which lat complementary to a portion of the hepatitis B virus (HBV) RNA. The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides containing a sequence which is complementary to at least two non- contiguous regions of an HBV nucleic acid, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection

```
The present sequence represents a synthetic oligonucleotide HBV43Ma which
                            is complementary to a portion of the hepatitis B virus (HBV) RNA. The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides containing a sequence which is complementary to at least two non-contiguous regions of an HBV nucleic acid, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            The present invention describes a single-stranded DNA probe (I) comprising in 3'-5' order, an anti-target nucleic acid segment, a (-)-promoter segment functionally linked to the anti-target segment, and a nucleic acid reporter segment. The probe is useful for testing a sample of a nucleic acid for the presence of a target nucleic acid segment or for detecting a target nucleic acid segment or also be used for the detection of hepatitis B virus (HBV). The probe nucleic acid segment contains the present about the detection of hepatitis B virus (HBV). The present sequence represents a bacteriophage SPG RNA polymerase promoter sequence sequence
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Single-stranded DNA probe comprising an anti-target nucleic acid, a (-)-promoter segment linked to the anti-target segment and a reporter segment, useful for detecting a target nucleic acid, e.g. hepatitis B
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       from the present invention. The composition is useful for the purification of nucleic acids. The composition can be used to process large quantities of nucleic acid samples, because it does not involve the particles being centrifuged or the fluids being centrifuged or the fluids being centrifuged or were used to amplify HBV DANA fragments. The amplified fragment can be

                                                                                                                                                                                                                       The present sequence represents a synthetic oligonucleotide HBV-87b which contains a sequence which is complementary to at least two non-contiguous regions of a hepatitis B virus (HBV) nucleic acid. The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides complementary to a portion of the HBV RNA, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection
                                                                                                                                                 Oligo:nucleotide(s) complementary to hepatitis B virus (HBV) sequences used in the detection and treatment of HBV infection.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            a

                  The present sequence represents a synthetic oligonucleotide HBV88Mb which is complementary to a portion of the hepatitis B virus (HBV) RNA. The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides containing a sequence which is complementary to at least two non-contiguous regions of an HBV nucleic acid, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection
                                                                                                                                                                                                                                                                                                                                                                                                                          .. .30

The present invention describes a method of screening for an antiviral agent by the protein-priming activity of hepatitis B virus (HBV) DNA polymerase. Also described is developing an antiviral agent with a high selectivity to HBV which can be used for high-throughput screening. The present sequence represents an RNA oligonucleotide which is used in the exemplification of the present invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Single-stranded DNA probe comprising an anti-target nucleic acid, a (-)-promoter segment linked to the anti-target segment and a reporter segment, useful for detecting a target nucleic acid, e.g. hepatitis B
                       Screening of antiviral agents by protein-priming activity of hepatitis virus DNA polymerase.

                                                                                                                                                                                                                                                                                                                                                                                                                     The present sequence represents a synthetic oligonucleotide HBV-87Mb which contains a sequence which is complementary to at least two noncontiguous regions of a hepatitis B virus (HBV) nucleic acid. The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides complementary to a portion of the HBV RMA, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection
                                                                                                                                                                                                                                                                                                                                    Oligo:nucleotide(s) complementary to hepatitis B virus (HBV) sequences used in the detection and treatment of HBV infection.

The present invention describes a single-stranded DNA probe (1) comprising in 3.-5 order, an anti-target nucleic acid segment, a (-)-promoter segment functionally linked to the anti-target segment, and a nucleic acid reporter segment. The probe is useful for testing a sample of a nucleic acid for the presence of a target nucleic acid segment or for detecting a target nucleic acid segment or also be used for the detection of hepatitis b virus (HBV). The probe may agenence represents a bacteriophage SPG RNA polymerase promoter sequence which is used in an example from the present invention. (Updated on 15-SEP-2003 to standardise OS field)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Sequence 64 BP; 14 A; 22 C; 4 G; 24 T; 0 U; 0 Other;

The present invention relates to hepatitis B virus (HBV) strain FR1, genotype G DNA encoding PreCore/Core protein, HBpol, envelope (PreS1, PreS2 and surface antigen HBBAg) and HBX proteins. HBP genotype G nucleic acids and surface artispen HBAg) and HBX proteins. HBV genotype G nucleic acids and polypeptides are useful for diagnosing, prognosing and treating infections caused by HBV genotype G. They can be used in a vaccine to incleic acids and antibodies are useful for detecting HBV genotype G in a sample or diagnosis of HBV genotype G infection. The presence of HBV genotype G statistically correlates with the presence of liver damage cand/or liver cancer in the subject. The HBV genotype G core insert peptide encoding nucleic acid is useful for designing monitoring assays to study and predict the evolution of anti-HBe and anti-HBc antibodies and HBAG (genotype G e antigen) in patients infected with HBV. The antibodies or antigens of HBV genotype G are useful for identifying a stage of liver disease caused by HBV genotype G. The present sequence is a hepatitis B virus (HBV) strain FRI, genotype G DNA fragment encoding e
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Novel hepatitis B virus genotype G, nucleic acids encoding virus, polypeptides encoded by nucleic acids, useful for preparing vaccine to treat or prevent the hepatitis B virus genotype G infection in a subject.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Zoulim F, Fried M;

genotype G DNA encoding Precore/Core protein, HBpol, envelope (Presi, Press and surface antigen HBaAg) and HBX proteins. HBvG envelope (Presi, Press and surface antigen HBaAg) and HBX proteins. HBV genotype G muclatic acids and polypeptides are useful for disgnosing, prognosing and treating infections caused by HBV genotype G. They can be used in a vaccine to treat or prevent HBV genotype G infection. The HBV genotype G derived mucleic acids and antibodies are useful for detecting HBV genotype G in a sample or disgnosis of HBV genotype G infection. The presence of HBV genotype G statistically correlates with the presence of liver damage and/or liver cancer in the subject. The HBV genotype G core insert peptide encoding nucleic acid is useful for designing monitoring assays to study. A predict the evolution of anti-HBC and anti-HBC antibodies
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Novel hepatitis B virus genotype G, nucleic acids encoding virus, polypeptides encoded by nucleic acids, useful for preparing vaccine to treat or prevent the hepatitis B virus genotype G infection in a subject.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   and HBeÂg (genotype G e antigen) in patients infected with HBV. The artibodies or antigens of HBV genotype G are useful for identifying a stage of liver disease caused by HBV genotype G. The present sequence is a hepatitis B virus (HBV) strain FRI, genotype G DNA fragment
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Zoulim F, Fried M;

(GENE-) GENELABS TECHNOLOGIES INC.

AW, Laurance ME, Michelotti EF; , Thomas RL, Kongpachith A, Sheppard LT; Latour DR, Starr DB, Tam Velligan MD, Latou Lim MY, Bruice TW; Kim JP,

WPI; 2002-130595/17.

New nucleic acid regulatory sequences, which are able to regulate expression of a gene operably linked to a promoter, useful for regulating the expression of transgenes and for treating e.g., cancer and immunological diseases.

Disclosure; Fig 1A; 95pp; English.

The invention describes an isolated nucleic acid regulatory sequence for a cyclin D1 promoter, a CD4OL promoter, vancomycin-resistant enterococci (VRE) promoter, an HBV promoter, androgen receptor (RA) promoter, Human epidermal growth factor receptor 2 (HBR2) promoter, or a beta lattamase (Bla) promoter. Transcription regulatory sequences may be used to requlate expression of the endogenous, autologous or heterologous genes operably linked to the promoter, and may be incorporated into heterologous nucleic acid constructs for use in regulated expression of transgenes. Regulated expression of cyclin D1 can be used in cancer therapies, such as breast, colon or pancreatic cancers and familial adenomatous polyposis. Regulation of the activity of CD4OL gene promoter may be used in the treatment of immunological disorders, such as autoimmune diseases e.g. multiple sclerosis (MS), systematic luques erythematosus (SLE), graft-vs-host disease (GVHD) and rheumatoid

arthritis. Regulated expression of genes under the control of the HBV (hepatitis B)-specific core, pre-5 and X promoters can be used in the therapy of HBV disease, chronic hepatic insufficiency, cirrhosis, hepatocellular carcinoma, and in the regulated expression of liver specific genes. Regulated expression of the vanH gene promoter can be used in treatment of Enterococcus infection, while regulated expression of the androgen receptor gene can be used in the treatment of prostate cancer. This sequence represents the hepatitis B virus core promoter the regulatory regions of which are described in the method of the invention 888888888888888

WPI; 2002-098223/13. P-PSDB; AAE17018. New proteins comprising a modified hepatitis B core antigen, useful as a vaccine in prophylactic or therapeutic vaccination of the human or animal body, particularly against hepatitis B virus infection.

Disclosure, Page 38-39; 40pp; English.

The invention relates to modified proteins comprising hepatitis B virus (HBV) core antigen (HBCAg) wherein one or more of the four arginine repeats has been deleted and the protein comprising the C-terminal cysteine of HBCAg. The deleted region may be replaced by an epitope from a protein other than HBCAg, in which case the HBCAG acts as a carrier to

therapeutic vaccination of the human or animal body, particularly against therapeutic vaccination of the human or animal body, particularly against HBV. The nucleic acid encoding the protein may be used in gene therapy or DNA vaccination protocols. The chimeric protein or its nucleic acid may also be used as the basis of a prophylactic vaccine against a range of diseases, e.g. HBV, hepatitis A virus (HAV), hepatitis C virus (HCV), influenza, foot-and-mouth disease, polio, herpes, rabies, acquired immunodeficiency syndrome (AIDS), dengue fever, yellow fever, malaria, diarrhoea, meningitis or gonorrhea. The present sequence is a DNA encoding Hepatitis B virus core antigen (HBCAG)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Hepatitis B (HB) core antigen fusion proteins, useful as vaccines for th
prophylactic or therapeutic treatment of humans or animals against e.g.
HB virus, viral hepatitis, hepatitis C virus, influenza, or foot-and-
   present the epitope to the immune system. This chimeric protein or its
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Hepatitis B virus core antigen; HBcAg; prophylactic; viral hepatitis; therapeutic; vaccine; acquired immune deficiency syndrome; influenza; polio; herpes; rabies; AIDS; foot-and-mouth disease; ds.

(HBCAg) fusion proteins and polynucleotides encoding such proteins. Sequences of the invention are useful in methods of prophylactic or therapeutic vaccination or to manufacture medicaments for prophylactic or therapeutic vaccination of the human or animal body sgainst HBV, e.g. against viral hepatitis. They are also useful as a prophylactic vaccine against e.g. hepatitis c virus, influenza, polio, herpes, rables, acquired immune deficiency syndrome (AIDS) or foot-and-mouth disease. The
                                                                                       acquired immune deficiency syndrome (AIDS) or foot-and-mouth disease. The present sequence is a DNA encoding hepatitis B virus core antigen (HBCAg)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           The invention relates to a method of introducing nucleic acid molecules to an animal which comprises administering a composition comprising two or more gene delivery vehicles to an animal at the same time and same site via a single administration device. The method is useful for introducing nucleic acid molecules to an animal, preferably humans for
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Introducing nucleic acid molecules to an animal or human, useful for treating diseases including cancer, genetic diseases, arthritis or AIDS comprises administering a composition comprising two or more gene delivery vehicles.
                                                                                                                                                                                             Gaps

treating diseases including cancer, genetic diseases, arthritis or AIDS. The method can also be administered to plants using traditional methods. The introduction of multiple or more than one nucleic acid molecule at one time provide significant advantages because multiple nucleic acid molecules can provide complementary substances or activities to a single nucleic acid molecules is much less than engineering a single nucleic acid molecules is much less than engineering a single molecule is multiple molecules, there is less chance that one substance or activity will sterically hinder or otherwise interfere with another substance or activity. The use of multiple molecules also permits systems subject to different substances or activities from expression control of different activity activity used of activity activities from expression control of different substances or activities. The present sequence represents the HBV precore/core DNA.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Precore; core; coding region; hepatitis B; virus; HBV; plasmid; KSII+; KSII+HBpc/c; pAMG; deletion; frameshift; PCR; overlap extension; SK+ HBe; primers; mutation; hepatocellular carcinomas; class-I; cytotoxic T-lymphocyte; CTL; hepatitis C; infection; ss.

containing the entire precore/core region, into the BamHI site of KSII+. The precore/core region of plasmid KSII+HBpc/p was sequenced and was found to contain a single base pair deletion which causes a frameshift at codon 79 which results in two consecutive in-frame TAG codons. This deletion was corrected by PCR overlap extension in plasmid SK+ HBe using mutation may also be corrected using the primers given in AAQ47015-18 in four separate reactions. The a separate series of reactions. The isolated HBV precore/core region may be used in a method to induce potent class-I restricted protective and therapeutic cytoxic T-lymphocyte (TLI) response, and a humoral response for the treatment of hepatitis B and C infections, as well as hepatocellular carcinomas. (Updated on 25-MAR-2003 to correct PN field.)

ส บ

This sequence represents the entire precore/core coding region of hepatitis B virus (HBV) isolated from the plasmid KSII+HBpc/c. This plasmid was created by ligating a 1.8 kb fragment of plasmid pAM6

Example 2; Fig 2; 110pp; English.

antigen.

introducing nucleic acids into an animal, by administration of a composition comprising two or more GDVs, in combination with a carrier or contained comprising two or more GDVs, in combination with a carrier or contained within the GDV, or directs expression of at least one substance (or biologically active nucleic acid) in host cells containing the GDV. The two GDVs collectively direct the expression of at least two different substances, or direct the expression of at least two different GDVs differ in one or more biological functions. The GDVs can be used for destroying hepatitis C carcinoma cells, for treating HBV (when a GDV contains an immunogenic HBV fragment such as this sequence). The GDVs can also be used for directing expression of non-tumourigenic, tumour associated antigens (such as altered ras gene), altered p53 gene, and (GDV) of the invention, and is used as an immunogenic portion of a HBV altered mucin. (Updated on 27-AUG-2003 to correct OS field.) \$

HBV Novel isolated and/or purified hepatitis B virus polypeptide and polynucleotide sequences that are phylogenetically different from genotype A-F molecules, useful for HBV diagnosis, prophylaxis and therapy

Claim 3; Fig 7; 94pp; English.

The invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Burope and the USA. The invention relates to a fully defined sequence of 3248 nucleotides as given in sepecification, a sequence with 92% identity to the given sequence, or sequence that is degenerate to the mentioned sequences. These polynucleotides are useful for HBV genotyping. The proteins encoded by AAH77569/

The invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Europe and the USA. The invention sequence that is degenerate to the mentioned sequence. These specification, a sequence with 92% identity to the given sequence, or sequence that is degenerate to the mentioned sequences. These polymucleotides are useful for HBV genotyping. The proteins encoded by the polymucleotides are useful for detecting antibodies in a biological sample. Ligands that bind to the proteins and for detecting the proteins are useful for detecting the proteins and sainst the proteins are useful for detecting the proteins and sainst the proteins are useful for detecting the proteins and so useful for preparing a vaccine or medicament for treating HBV infections. The present sequence is provided in an alignment of precore/CC an HBV genotype A strain (HBVXCPS) and 7 strains (FRI, FRI, US3, US1, US3, US1) of HBV genotype G
                                                                                                                                                                                                                                                                                                                                                                                                                                                             HBV
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Gaps

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           The invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Europe and the USA. The invention relates to a fully defined sequence of 3248 nucleotides as given in sequence that is degenerate to the mentioned sequences. These polymucleotides are useful for HBV genotyping. The proteins encoded by the polymucleotides are useful for the proteins and antibodies in a biological sample. Ligands that bind to the proteins and antibodies directed against the proteins are useful for detecting the proteins and sor detecting the proteins are useful for detecting the proteins and sor detecting the proteins are useful for detecting the proteins and sor medicament for treating HBV infections. The present sequence is provided in an alignment of precore/Core sequences of an HBV genotype A strain (HBVXCPS) and 7 strains (FR1, FR2, US1, US3, US6, US7, US9, US10) of HBV genotype G

```
The invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Burope and the USA. The invention relates to a fully defined sequence of 3248 nucleotides as given in sequence with 92% identity to the given sequence, or sequence that is degenerate to the mentioned sequences. These polynucleotides are useful for HBV genotyping. The proteins encoded by the polynucleotides are useful for detecting antibodies in a biological sample. Ligands that bind to the proteins and antibodies directed against the proteins are useful for detecting the proteins and spreading the mediane the receive proteins for treating the sequence is provided in an alignment of precence/Core sequences of the W genotype A strain (HBVXCPS) and 7 strains (FR1, FR2, US1, US3, US6, US7, US9, US10) of HBV genotype G

Hepatitis B virus.

US2002141974-A1.

03-OCT-2002

The present invention relates to a method for treating hepatitis B or C directions. The method involves administering a vector construct that directs the expression of at least one immunoganic portion of hepatitis B virus (HBV) antigen, containing HBeAg, HbcAg, HbcAg, S. Pre-S1, Pre-S2, open reading frame (ORF) 5, ORF 6, HBV pol or HBxAg or co-expression of a least one immunogenic portion of a HBV antigen and at least one immunogenic portion of a hepatitis C virus (HCV) antigen. The vectors are useful in gene therapy, particularly for treating or preventing hepatitis The present sequence is a PCR primer used for amplifying Hepatitis B virus adw strain precore/core mutant DNA.

The invention relates to a method for treating hepatitis C infections in a warm-blooded animal comprising administering a vector construct which directs the expression of at least one immunogenic portion of a hepatitis c antigen, where an immune response is generated, and alternatively, in combination with an immunodulatory cofactor. The invention also relates to a vector construct which directs the co-expression of at least one immunogenic portion of a hepatitis B antigen and at least one immunogenic portion of a hepatitis C antigen, an immunogenic portion of the polyprotein antigen, or an immunogenic portion of the polyprotein antigen and an immunoregulatory cofactor. A recombinant virus carrying the vector construct is selected from poliovirus, rhinovirus, pox virus, canary pox virus, vaccinia virus, influenza virus, adenovirus, parvovirus, adenovirus, herpes virus, SV40, HIV, measles, corona virus or singles virus. This sequence represents hepatitis B virus precore/core

within warm-blooded animals comprising administering to a warm-blooded animal a vector construct which directs the expression of at least one immunogenic portion of an antigen derived from an intracellular pathogen, and a protein having the immunogenic portion of the antigen to generate an immune response. The method is useful for treating intracellular infections or diseases including viral infections (e.g. hepatitis B virus (HBW), hepatitis C virus (HCW), herpes simplex virus (HSW), human immunodeficiency virus (HIV) or feline immunodeficiency virus (FIV)), parabitic infections (e.g. rickettsia, leishmaniasis or malaria) and certain bacterial diseases (e.g. leishmaniasis or malaria) and riss sequence represents hepatitis B virus DNA used in the method of the

```
The coding sequences of the preC and C Ags of HB virus were inserted into Autograph californica muclear polyhedrosis virus (ACNPV) transfer vector packMixTyc and packMixTyc recombinant transfer vectors were called packMixTyc and packMixTyc. Following cotransfection with infectious AcNPV DNA, recombinant baculoviruses were obtained - YMIXYc and YMIXYc. It was determined that all the HBcAg and HBpcAg was cell associated and that the yield of purified HBcAg was of the order of 5 mg per liter of 1x10(9) infected cells. Such Ag may be useful in vaccines. (Updated on 25-MAR-2003 to correct PR field.)
                                                                                                   New plasmid replicon for inserting several genes into vector - contg. two polypeptide expression structures, and derived viral vectors for infecting insect cells.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Sequence 660 BP; 156 A; 171 C; 143 G; 189 T; 0 U; 1 Other;

De Gendt S;

human hepatitis B virus the complete independence of a new human hepatitis B virus that a high prevalence in patients of an eventual genotype was found with a high prevalence in patients chronically infected with HBV and residing in Burope and the USA. The invention relates to a fully defined sequence of 3248 mucleotides as given in specification, a sequence with 92% identity to the given sequence, or specification, a sequence with 92% identity to the given sequence, or polynucleotides are useful for mentioned sequences. These polynucleotides are useful for detecting antibodies in a biological the proteins are useful for detecting antibodies in a biological the proteins are useful for detecting the proteins and for detecting the proteins and sor detecting the proteins and sor detecting the proteins and antibodies directed against the proteins are useful for detecting the proteins and sor detecting the proteins and antibodies of a detecting the proteins and an elso useful for preparing a vaccine or medicament for treating HBV infections. The t sequence is provided in an alignment of preCore/Core sequences of genotype A strain (HBVXCPS) and 7 strains (FR1, FR2, US1, US3, The invention relates to the complete nucleic acid sequence of Claim 3; Fig 7; 94pp; English.

US6, US7, US9, US10) of HBV genotype G present sequence is

Sequence 664 BP; 146 A; 160 C; 144 G; 208 T; 0 U; 6 Other;

Modulating a systemic immune response to a peptide in a mammal comprises transmucosally administering a macromolecular aggregate of the peptide.
                                                                                                                                                                                                                                                                                                                                                                                                                                   a HBV protein. A monomolecular peptide is useful for the induction of oral tolerance when induction of systemic immunity is undesirable, e.g. in cases of chronic infections.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Sequence 669 BP; 155 A; 170 C; 148 G; 196 T; 0 U; 0 Other;

The present invention relates to hepatitis B virus (HBV) strain FRI, press and surface antigen HBAG) and HBX protein, HBpOl, envelope (Presi, Press and surface antigen HBAG) and HBX proteins. HBV genotype G nucleic acids and polypeptides are useful for diagnosing, prognosing and treating infections caused by HBV genotype G. They can be used in a vaccine to treat or prevent HBV genotype G. They can be used in a vaccine to nucleic acids and antibodies are useful for detecting HBV genotype G derived nucleic acids and antibodies are useful for detecting HBV genotype G in sample or diagnosis of HBV genotype G infection. The presence of HBV genotype G statistically correlates with the presence of HBV peptide encoding nucleic acid is useful for designing monitoring assays and HBAG (genotype G entiged) in patients infected with HBV. The antibodies or antigens of HBV genotype G are useful for identifying a
                                                                                                                                                                                                                                                                                                                       \[\text{transl_except= (pos:4. .6, aa.Xaa)}\]
\[\text{transl_except= (pos:82. .84, aa.Xaa)}\]

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          The invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Burope and the USA. The invention relates to a fully defined sequence of 1348 nucleotides as given in specification, a sequence with 92% identity to the given sequence, or sequence that is degenerate to the mentioned sequences. These the polynucleotides are useful for the yenotyping. The proteins encoded by the polynucleotides are useful for detecting antibodies in a biological sample. Ligands that bind to the proteins and antibodies directed against the proteins are useful for detecting the proteins and for detecting the proteins and succeeding a vaccine or medicament for treating HBV infections. The present sequence is the complete coding sequence of the HBV preCore/Core
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Novel isolated and/or purified hepatitis B virus polypeptide and polynucleotide sequences that are phylogenetically different from HBV genotype A-F molecules, useful for HBV diagnosis, prophylaxis and

The invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients Chronically infected with HBV and residing in Europe and the USA. The invention relates to a fully defined sequence of 3248 nucleotides as given in specification, a sequence with 92% identity to the given sequence, or sequence that is degenerate to the mentioned sequences. These polynucleotides are useful for HBV genotyping. The proteins encoded by the polynucleotides are useful for detecting antibodies in a biological sample. Ligands that bind to the proteins and for detecting the proteins and for detecting the proteins and for detecting the proteins are useful for detecting the proteins and for detecting many and the proteins are useful for preparing a vaccine or medicament for treating HBV infections. The present sequence is provided in an alignment of precore/Core sequences of an HBV genotype A strain (HBVXCPS) and 7 strains (FRI, FRZ, USI, USS, USI), USS, USI, USS, USI) of HBV genotype G

                                                                                                                                                                                                                                                                                                                                                                                                        The cloned HBV DNA can be used to engineer plasmids for HBCAg synthesis in bacteria. The DNA may be fused to a gene for beta galactosidase. The recombinant protein can be used for immuno- assays, to raise antibodies, and in vaccines. See also AAN82265 and 66. this purputation to the regions of the registatory and cooling regions of the XIS component in the X-myc construct. The invention comprising of the XIS component in the X-myc construct. The invention comprising of the HBV XIS gene and c-myc gene. The myc gene is known to comprising of the HBV XIS gene and c-myc gene. The myc gene is known to brotein that has amino acids S8-154 of HBV XIS and a murine c-myc protein, respectively. A transgenic mouse contending the transgene construct is useful for screening acandidate substance (CS), to determine whether CS promotes hepatocellular carcinoma. This is construct be exposed a candidate substance (CS), to determine by exposing a transgenic mouse to CS, and monitoring the mouse core for the development of hepatocellular carcinoma, where an increase in the development of hepatocellular carcinoma, where an increase in the transgenic mouse not exposed to CS, indicates that CS promotes a compared to the development of hepatocellular carcinoma in a transgenic mouse not exposed to CS, indicates that CS promotes CC for call and tissue culture. The transgenic mine employed as a source constrained by transgenic mine for hepatocellular carcinoma are superior to the HBV XIS-c-myc transgene for hepatocellular carcinoma are superior to any transgenic minel models bystem for hepatocellular carcinoma in that carcinoma tiver tumours in all lobes causing death of the affected mainals in 20-22 weeks, that is faster than the time taken by the other caransgenic animals to even develop a tumour
                                                                                                                                                                                                                                                          This polynuclectide represents the sequence of the regulatory and coding
                                                                                                                                   New bicistronic hepatitis B virus (HBV) X15-c-myc transgene, useful for producing transgenic mouse model systems for human hepatocellular carcinoma, comprises HBV X15 transgene and c-myc transgene.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Fulminant hepatitis B virus; variant; FHBV; HBV; binding interaction;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Gape

The present sequence represents part of the genome of a fulminant the specification describes Hepatitis B virus (HBN) genotype D variant, nucleotides 1000 to 2500. The specification describes Hepatitis B virus (HBN) nucleotide and that has a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative regulatory element region, the enhancer II, core upstream regulatory sequence, basal core promoter region, or a mutation which leads to an X-peptide anno acid change to Cys or Met. The HBV variants of the proteins and HBV nucleic acid. Probes that hybridise to any of the proteins and the region are used to detect binding interactions between host or viral specified mutated regions are used to detect HBV-related disease. New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic. especially fulminant infection, but also severe chronic infection or serologically unusual forms of disease. Combinations of the specified mutations are associated with fulminant infections, probably because they reduce the ability to bind inhibitory proteins in the host cell Gaps ö 100.0%; Score 20; DB 2; Length 1334; 85.0%; Pred. New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.

Disclosure, Fig 5, 85pp, English.

The present sequence represents part of the genome of a fulminant Hepatitis B virus (FHBV) genotype D variant, nucleotides 1000 to 2500.

The specification describes Hepatitis B virus (HBV) nucleic acid that has a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative regulatory element region, or a mutation which leads to a sequence/ basal core promoter region, or a mutation which leads to an X-peptide amino acid change to Cys or Met. The HBV variants of the invention are used to detect binding interactions between host or viral proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV-related disease, especially fulminant infection, but also severe chronic infection or serologically unusual forms of disease. Combinations of the specified mutations are associated with fulminant infections, probably because they mutations are associated with fulminant infections, probably because they reduce the ability to bind inhibitory proteins in the host cell

The present sequence represents part of the genome of a fulminant Hepatitis B virus (FHBV) genotype D variant, nuclectides 1000 to 2500.

The specification describes Hepatitis B virus (HBV) nucleic acid that has a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative regulatory element region, to a mutation which leads to an x-peptide amino acid change to Cys or Met. The HBV variants of the reported amino acid change to Cys or Met. The HBV variants of the proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect binding interactions between host or viral proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV-related disease, especified mutated forms of disease. Combinations of the specified mutations are associated with fulminant infections, probably because they reduce the ability to bind inhibitory proteins in the host cell
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        ö
                                                                                                                                                                                                                                                                                                                                                                                                                                               New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Gaps

```
The present sequence represents part of the genome of a fulminant Hepatitis B virus (FHBV) genotype D variant, nucleotides 1000 to 2500. The specification describes Hepatitis B virus (HBV) nucleic acid that has a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative regulatory element region, the enhancer II/ core upstream regulatory sequence/ basal core promoter region, or a mutation which leads to an X-peptide amino acid change to Cys or Met. The HBV variants of the invention are used to detect binding interactions between host or viral proteins and HBV nucleic acid. Probes that hybridise to any of the proteins and environment of the contractions are used regions are used to detect HBV-related disease,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   because they

The present sequence represents part of the genome of a fulminant Hepatitis B virus (FHBV) genotype D variant, nucleotides 1000 to 2500. The specification describes Hepatitis B virus (FHBV) undicic acid that has a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative crequiatory element region, the enhancer I/ core upstream regulatory squence/ basal core promoter region, or a mutation which leads to an X-sequence/ basal core promoter to Met. The HBV variants of the peptide amino acid change to Cys or Met. The HBV variants of the proteins and HBV nucleic acid. Probes that hybridise to any of the proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related clisease.

Specified mutated regions are used to detect Combinations of the specified mutations are associated with fulminant infections, probably because they reduce the ability to bind inhibitory proteins in the host cell

New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.

ò - useful for, e.g. detection of binding interactions between host viral proteins and HBV nucleic.

Disclosure; Fig 5; 85pp; English

The specification describes Hepatitis B virus (HBV) nucleotides 1000 to 2500. The specification describes Hepatitis B virus (HBV) nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative regulatory element region, the enhancer II/ core upstream regulatory sequence/ basal core promoter region, or a mutation which leads to an X-peptide amino acid change to Cys or Met. The HBV variants of the invention are used to detect binding interactions between host or viral proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV-related disease, especially fulminant infection, but also severe chronic infection or serologically unusual forms of disease. Combinations of the specified mutations are associated with fulminant infections, probably because they reduce the ability to bind inhibitory proteins in the host cell sequence represents part of the genome of a

```

New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.

Disclosure; Fig 5; 85pp; English.

```
The present sequence represents part of the genome of wild type Hepatitis B virus genotype D, nucleotides 1000 to 2500. Mutations occur in this region in fulminant hepatitis B virus (FHBV) patients. The specification describes Hepatitis B virus (FHBV) patients. The specification describes Hepatitis B virus (HBV) nucleic acid that has a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to F) in the last two of the enhancer I region, the negative requlatory element region, the enhancer II/ core upstream regulatory sequence/ basal core promoter region, or a mutation which leads to an X-peptide amino acid change to Cys or Met. The HBV variants of the invention are used to detect binding interactions between host or viral proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV-related disease, especially fulminant infection, but also severe chronic infection or scrologically unusual forms of disease. Combinations of the specified mutations are associated with fulminant infections, probably because they reduce the ability to bind inhibitory proteins in the host cell
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Gaps

Hepatitis B virus (FREW) genoty pour out the general conditions of a virus (FREW) genoty pour out the specification describes Hepatitis B virus (HBV) nucleic acid that has a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative regulatory element region, the enhancer II/ core upstream regulatory peptide amino acid change to Gy sor Met. The HBV variants of the invention are used to detect binding interactions between host or viral proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV-related disease, especially fulminant infection, but also severe chronic infection or serologically nunsual forms of disease. Combinations of the specified
                                                                                                                                                                                                                                                                                                                                         New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              probably because they

New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.

Hepatitis B virus (FREV) genotype D variant, mucleotides 1000 to 2500. The specification describes Hepatitis B virus (HBV) nucleic acid that has a mutation (1.e. alteration from the normal nucleotide in any of the genotypes A to P) in at least two of the enhancer I region, the negative region, the enhancer II/ core upstream regulatory sequence/ basal core promoter region, or a mutation which leads to an X-peptide amino acid change to Cys or Met. The HBV variants of the invention are used to detect binding interactions between host or viral proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV-related disease, especially fulminant infection, but also severe chronic infection or serologically unusual forms of disease. Combinations of the specified mutations are associated with fulminant infections, probably because they reduce the ability to bind inhibitory proteins in the host cell sequence represents part of the genome of a fulminant Disclosure; Fig 5; 85pp; English.
